

4 Channel Stepper Driver Shield

for Arduino $^{^{\mathrm{TM}}}$ and Raspberry-PI $^{^{\mathrm{TM}}}$

Technical Data

Features

- ArduinoTM UNO Shield standard form factor for simple integration into any Arduino project
- Frees up the ArduinoTM IO lines normally used for motor control
- I²C interface for simple connection to Arduino or Raspberry-PI
- On-board 5Volt 3Amp regulator, with heat-sinking, for stepper motor and external 5V supply
- 8bit (1 to 255) level step speed control for each motor
- 16bit (1 to 65535) number of steps control for each motor
- Movement complete status for each motor
- Global activation control ensures all motors start moving together, important for 2/4 wheel drive rovers
- I²C address links allow up to four [4] shields to be used together to provide up to 16 motors
- LVD, RoHS and WEEE compliant product

Description

The Designer Systems DS-STX4.S is a four [4] channel 5V or 6-12V (jumper selectable) Unipolar stepper motor driver with advanced control features.

Specifically targeted at the Arduino UNO board user [all other Arduino boards supported] and the Raspberry-PI the STX4.S features high speed I²C communication for easy project integration and smooth speed control.

Once connected each stepper motor can be stepped in either direction a number of steps (with speed control), continually stepped (with speed control), stopped (with holding torque or completely off), with selectable 1 or 2 phase excitation, by simply writing a value to an internal register over the connected I²C interface.

The STX4.S supports all 5-12V unipolar (5 wire) stepper motors (with a minimum winding resistance of 20R [250mA]) and also provides global activation of new stepper positions & movement complete registers for superior control.

The STX4.S provides a high power regulator capable of supplying

DS-STX4.S

5V @ 3A to the connected servos from an external Li-Pol or Ni-MH battery pack of 7.2 to 8.4V and a 5V @ 1A USB A power output to power an externally connected Arduino board or Raspberry-Pi. Alternatively a jumper selection allows servos with a maximum 12V operating voltage to be used. The on-board I²C pull-ups are jumper configurable to allow disconnection when connecting to the Raspberry-PI, which has its own pull-ups.

Applications

The STX4.S has applications in robotics, including 2 and 4 wheeled rovers, process control & sensor manipulation when used in conjunction with standard unipolar stepper motors.

Selection Guide

DC	icenon duide	
	Description	Part Number
4	Channel Stepper Driver Shield	DS-STX4.S
24	4mmD 5V 1/16 ratio (5mmD shaft) unipolar stepper motor	DS-STMOT1
5v	way ZHR connector to free ends 200mm	DS-STCAB1

Raspberry-PI, Arduino, NANO, UNO & MEGA are trademark

Power requirements

The DS-STX4.S takes the power necessary for operation (approx. 2-25mA) and the power for the USB type 'A' power output and stepper motors (1-3A) from an external battery / mains adaptor.

The input voltage range is 6 - 12VDC which can be applied directly to the stepper motors or through the on-board regulator which provides a clean regulated 5V supply.

The stepper motor supply for motors 1&2 (Jumper 1) and 3&4 (Jumper 2) can be selected as follows:

6-12VDC supply (A position):

5VDC supply (B position):

Refer to the voltage rating of the stepper motors you wish to use before configuring the jumpers. Stepper motors rated at 5V may be driven with a 6V supply to reduce power dissipation in the 5V 3A regulator.

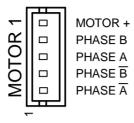

The USB type 'A' power output provides a 5V @ 1A maximum supply to power a Raspberry-Pi or Arduino platform.

Connection of the external supply battery / mains adaptor - to the STX4 module is through a two (2) way pluggable screw terminal block marked '6-12VDC @ 3A Max'.

Note: This supply is NOT reverse connection protected but is marked with a series of '++++' signs to denote positive.

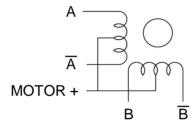

Stepper motor connection

The stepper motor connections are marked 'MOTOR 1' to 'MOTOR 4' and consist of a five (5) pin JST ZHR 1.5mm pitch connector pinned as follows:

This connection is standard for most 24mmD stepper motors, such as the DS-STMOT1, but there is also a pre-made 200mm JST ZHR cable available, DS-STCAB1, and the JST ZHR mating receptacle and pins are also available from Farnell electronics as items 2078162 and 1830898 respectively.

Most unipolar stepper motor phases are wired as follows:

It is recommended that you double check your motor phase connections before power application.

Six wire stepper motors are also supported by connecting the two centre taps both to MOTOR +.

I²C connection

The I²C connections are marked 'SDA' and 'SCL' and allow connection to the Arduino UNO board 'ANALOG IN' pins 4 and 5 or the Raspberry-PI GPIO port pins 3 and 5 (see Fig. 2.0) or another I²C Master device.

The DS-STX4.S is fitted with pull-up jumpers that can be configured to provide the source current necessary for I²C communication. The following jumpers should normally be set when using the UNO board, as long as the I²C bus does not have existing pull-up's provided by another device.

These jumpers <u>MUST</u> be removed when using the Raspberry-PI:

I²C communication

Up to four DS-STX4.S modules may be connected to the same UNO / Raspberry-PI board or I^2C bus and accessed individually using their own individual address.

The address is configured with the following jumpers:

The following table shows how the jumpers are placed for the different binary addresses:

Address xx	A0	A1
00 (default)	ON	ON
01	OFF	ON
10	ON	OFF
11	OFF	OFF

The binary address (xx) above is used in conjunction with the device ID 11011xxD to form the complete device address i.e. if both jumpers are left connected (default) then the device address would be $1101100D_{\rm binary}$.

The 'D' bit determines if a read or a write to the STX4 is to be performed. If the 'D' bit is set '1' then a register read is performed or if clear '0' a register write.

To access individual registers a device write must be undertaken by the I²C Master which consists of a Start condition, device ID ('D' bit cleared), register to start write, one or more bytes of data to be written and a stop condition (see Figure 1.0 for I²C write protocol).

There are 17 individual registers that can be written within the STX4 that control output as follows:

	N ₇	N ₆	N ₅	N_4	N_3	N_2	N ₁	N_0	
STX I2C address									
1.	1	1	0	1	1	Χ	Χ	0

Servo global enable register								
X								
) X								

Each control register consists of five control bits defined as follows:

Bit (A) 1_{decimal} is the operate bit which when set activates the stepper being controlled.

Bit (B) 2_{decimal} is the reverse bit which reverses the direction of the stepper being controlled.

Bit (C) 4_{decimal} is the rotate bit which makes the stepper motor constantly rotate rather than step the number of steps defined in the step number register.

Bit (D) 8_{decimal} is the step bit which allows the stepper motor to be configured for normal or half-step oper-

Bit (E) 16_{decimal} is the hold bit which allows the stepper motor to hold its position (holding torque) once the number of steps have been made or go free (no holding torque).

Once all the required step & control registers have been set a write to the R17 (Global enable register) must be made to activate all the new settings.

Example.

To step motor 1 500 half-steps clockwise at 3mS per step and then hold in that position, first write:

Byte 1 (STX4 Adr)	11011000 _{binary}
Byte 2 (Register 0)	$0_{decimal}$
Byte 3 (Register 1)	25 _{decimal} , 19 _{hex}
Byte 4 (Register 2)	$1_{\text{decimal}}, 01_{\text{hex}}$
Byte 5 (Register 3)	232 _{decimal} , E8 _{hex}
Byte 6 (Register 4)	$12_{\text{decimal}}, 0C_{\text{hex}}$

then to activate write:

Byte 1 (STX4 Adr)	11011000 _{binary}
Byte 2 (Register 0)	17 _{decimal}
Byte 3 (Register 17)	$0_{decimal}$

The individual registers are broken down into:

Register 1 = 25 which sets bits A (enable motor), D (half-step) and E (hold on stop)

Register 2 & $3 = 500 \text{ (1E8}_{hex})$ split into register 2 = 01 and register 3 =

Register 4 = 12 which configures the step to 3mS (12x0.25mS = 3mS)

To read the status registers a device write then read must be undertaken by the Arduino / Raspberry-Pi / I²C Master. The write consists of a Start condition, device ID ('D' bit cleared), register to start read and a Stop condition.

This is followed by a read, which consists of a Start condition, device ID ('D' bit set), followed by data from the status register and terminated with a Stop condition (see Figure 1.1 for I^2C read protocol).

Status registers

There are 5 registers that can be read within the STX4 as follows:

	N ₇	N ₆	N ₅	N_4	N ₃	N_2	N ₁	N_0
1.	(I2C A 1 = STX4	1	0	1	1	Х	Х	1

Notes:

- 1.Minimum voltage given is required for normal operation whether stepper motor regulator is used or not.
- 2. Force cooling of the heat-sinks may be required if the 5V regulator is enabled and supply voltage in high.
- 3.Maximum value given is when the 5V regulator is disabled ie, the stepper motor voltage is the same as the supply voltage.
- 4. Values given are for stepper motors being not driven and driven.
- 5. Values given are based on maximum and minimum loading.

Calculating binary bit values:

The registers used above use the binary notation to allow the control of stepper motor operation, reversal, rotation type, step type and hold. Each register is made up of eight (8) bits, which can be set or cleared to produce the desired operation, the individual bits having a value associated with them as follows:

128	64	32	16	8	4	2	1
-----	----	----	----	---	---	---	---

If we take for example one of the stepper control registers we can see it is made up of five (5) separate bits A, B, C, D & E plus three unused bits UUU:

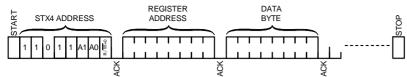

Stepper 1 control

- A = Operate (0 Stepper disabled 1 Stepper enabled)
- B = Reverse (0 Stepper normal 1 Stepper reversed)
- C = Rotate (0 Single step 1 Constant rotation)
- D = Step (0 Normal step 1 Half step)
- E = Hold (0 No hold on stop 1 Hold on stop)
- U = Unused

Each bit is defined to control a particular function for the stepper it controls, so if for example we wanted to enable stepper 1 we would need to set bit 'A' which controls the stepper operation. We know from the bit values defined above that the value associated with the 'A' bit is 1, so by writing this value to register 1 we can enable stepper 1. If we need to enable additional functions such as the constant rotation - 'C' - as well as the stepper enable, the value of this bit is added to the value written to the register i.e. 1 + 4 = 5. In addition we could also reverse the direction of rotation that would make the total value 1 + 4 + 2 = 7.

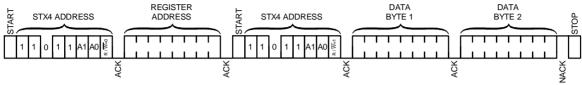

Figure 1.0 (I²C write protocol)

Multiple bytes may be written before the 'STOP' condition. Data is written into registers starting at 'REGISTER ADDRESS', then 'REGISTER ADDRESS' +1, then 'REGISTER ADDRESS' +2 etc.

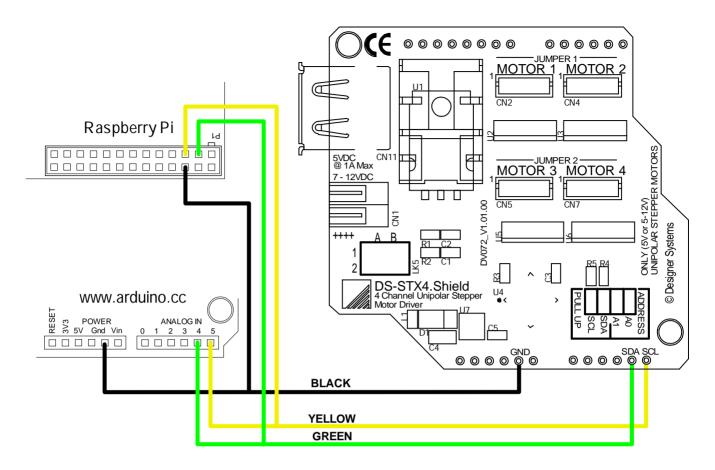

Each byte transfer is acknowledged 'ACK' by the STX4 until the 'STOP' condition.

Figure 1.1 (I²C read protocol)

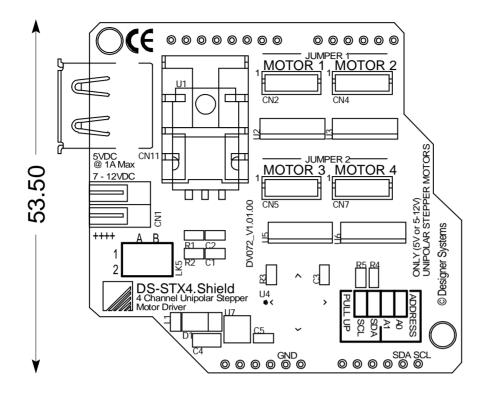

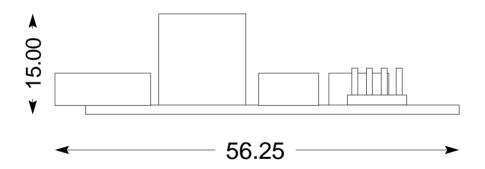

'DATA BYTE 1 & 2' are register values returned from the STX4. Each byte written is acknowledged 'ACK' by the STX4 , every byte read is acknowledged 'ACK' by the I²C Master. A Not-acknowledge 'NACK' condition is generated by the I²C Master when it has finished reading.
